Phleomycin
Selection antibiotic; cell culture tested
Catalog code: ant-ph-1, ant-ph-5
http://www.invivogen.com/phleomycin

For research use only
Version 18C26-MM

PRODUCT INFORMATION
Content
Phleomycin is supplied as a sterile filtered blue solution at 20 mg/ml in HEPES buffer. It is available in 2 pack sizes:
- ant-ph-1: 5 x 1 ml (100 mg)
- ant-ph-5: 25 x 1 ml (500 mg)

Storage and stability
- Phleomycin is shipped at room temperature. Store phleomycin at 4 °C or at -20°C. Avoid repeated freeze-thaw cycles.
- The expiry date is specified on the product label.
- Phleomycin is sensitive to high concentrations of acids but a short-term exposure to dilute acids can be tolerated.

Note: Phleomycin is stable for 1 month at room temperature.

QUALITY CONTROL
Each lot is thoroughly tested to ensure the absence of lot-to-lot variation.
- Endotoxin level: < 1 EU/mg
- Physicochemical characterization (including HPLC, pH, appearance)
- Cell culture tested: potency validated in phleomycin-sensitive and phleomycin-resistant bacterial, fungal and mammalian cells
- Non-cytotoxicity of trace contaminants: absence of long-term effects confirmed in phleomycin-resistant cells

BACKGROUND
Phleomycin is a selection antibiotic that is active against most bacteria, filamentous fungi, yeast, plant and animal cells. Use of phleomycin is recommended for cells poorly sensitive to Zeocin, i.e. filamentous fungi and yeast. Phleomycin resistance is conferred by the Sh ble gene from Streptothilicus hindustanus.
Phleomycin is a glycopeptide antibiotic of the bleomycin family, isolated from a mutant strain of Streptomyces verticillus. Although bleomycin antibiotics perturb plasma membranes, their activity is generally believed to be related to their ability to bind and intercalate DNA thus destroying the integrity of the double helix.

CHEMICAL PROPERTIES
Phleomycin is a mixture of structurally related antibiotics which differ by their terminal amine residues. They are in a copper chelated form giving the solution a blue color. The information below refers to Phleomycin D1.

CAS number: 11006-33-0
Empirical formula: C55H85O21N20S2Cu, HCl
Molecular weight: 1525

CONDITIONS OF SELECTION
Most cells growing aerobiically are killed by 0.1 to 50 µg/ml phleomycin. However, the sensitivity of cells is pH dependent, i.e. the higher the pH of the culture medium, the greater the sensitivity. Thus the concentration of phleomycin required for complete growth inhibition can be reduced by increasing the pH of the culture medium. In addition, the activity of phleomycin is reduced by a factor 2 to 3 in hypertonic media such as those used for protoplast regeneration.
Thus, using low salt media when possible decreases the amount of phleomycin needed.
Prior to each use, bring phleomycin to room temperature and gently vortex to homogenize before use.

- Escherichia coli
  The cells of the common Es. coli recipient strains (i.e. HB101, DH5α, MC1061) transformed by vectors carrying bleomycin resistant genes, such as Sh ble and Tn5, are resistant to phleomycin. Phleomycin-resistant transformants are selected in Low Salt LB agar medium (yeast extract 5g/l, Tryptone 10g/l, NaCl 5g/l, Agar 15g/l, pH 7.5) supplemented with 5 µg/ml of phleomycin. Plates containing phleomycin are stable for 1 month when stored at 4°C.
- Yeasts
  Phleomycin-resistant transformants of Saccharomyces cerevisiae are selected with 10 µg/ml of phleomycin in YEPD medium.
  Following transformation with plasmid DNA, yeast cells are diluted in YEPD medium and incubated in a shaker for phenotypic expression of the antibiotic resistance for 6 hours to overnight. Then the culture is chilled for 1 hour on ice before plating on YEPD medium (pH 7.0) supplemented with 10 µg/ml of phleomycin.
- Fungi
  Phleomycin-resistant transformants are selected with 10-50 µg/ml of phleomycin in the regeneration medium, depending on the sensitivity of the host strain. Selectivity can be increased by overnight incubation at 4 °C of the selection plates prior to incubation at growth temperature.
- Plant cells
  Phleomycin-resistant transfectants are selected with 5-25 µg/ml of phleomycin depending on the vegetal.
- Mammalian cells
  The working concentration of phleomycin for mammalian cell lines varies from 5 to 50 µg/ml. In a starting experiment we recommend to determine the optimal concentration of phleomycin required to kill your host cell line. The killing and the detachment of dead cells from the plate, especially at high cell density, can require a longer time compared to G418. Foci of phleomycin-resistant stable transfectants are usually individualized after 5 days to 3 weeks incubation, depending on the cell line.

GENERAL GUIDELINES
Successful transfection is influenced by many factors. The health and viability of the cell line, the quality of the nucleic acid used, the transfection reagent, the duration of transfection, and the presence or absence of serum can all play a part.

SAFETY CONSIDERATIONS
Phleomycin is a harmful compound. Refer to safety data sheet for handling instructions.
